

# Codeforces Round #245 (Div. 1)

## A. Xor-tree

time limit per test: 1 second memory limit per test: 256 megabytes input: standard input output: standard output

lahub is very proud of his recent discovery, propagating trees. Right now, he invented a new tree, called xor-tree. After this new revolutionary discovery, he invented a game for kids which uses xor-trees.

The game is played on a tree having n nodes, numbered from 1 to n. Each node i has an initial value  $init_i$ , which is either 0 or 1. The root of the tree is node 1.

One can perform several (possibly, zero) operations on the tree during the game. The only available type of operation is to pick a node *X*. Right after someone has picked node *X*, the value of node *X* flips, the values of sons of *X* remain the same, the values of sons of sons of *X* flips, the values of sons of s

The goal of the game is to get each node i to have value  $goal_i$ , which can also be only 0 or 1. You need to reach the goal of the game by using minimum number of operations.

## Input

The first line contains an integer n ( $1 \le n \le 10^5$ ). Each of the next n - 1 lines contains two integers  $u_i$  and  $v_i$  ( $1 \le u_i$ ,  $v_i \le n$ ;  $u_i \ne v_i$ ) meaning there is an edge between nodes  $u_i$  and  $v_i$ .

The next line contains n integer numbers, the i-th of them corresponds to  $init_i$  ( $init_i$  is either 0 or 1). The following line also contains n integer numbers, the i-th number corresponds to  $qoal_i$  ( $qoal_i$  is either 0 or 1).

#### **Output**

In the first line output an integer number Cnt, representing the minimal number of operations you perform. Each of the next Cnt lines should contain an integer  $X_i$ , representing that you pick a node  $X_i$ .

## **Examples**

# B. Working out

time limit per test: 2 seconds memory limit per test: 256 megabytes

input: standard input output: standard output

Summer is coming! It's time for lahub and lahubina to work out, as they both want to look hot at the beach. The gym where they go is a matrix a with n lines and m columns. Let number a[i][j] represents the calories burned by performing workout at the cell of gym in the i-th line and the j-th column.

lahub starts with workout located at line 1 and column 1. He needs to finish with workout a[n][m]. After finishing workout a[i][j], he can go to workout a[i+1][j] or a[i][j+1]. Similarly, lahubina starts with workout a[n][1] and she needs to finish with workout a[n][n]. After finishing workout from cell a[i][j], she goes to either a[i][j+1] or a[i-1][j].

There is one additional condition for their training. They have to meet in exactly one cell of gym. At that cell, none of them will work out. They will talk about fast exponentiation (pretty odd small talk) and then both of them will move to the next workout.

If a workout was done by either lahub or lahubina, it counts as total gain. Please plan a workout for lahub and lahubina such as total gain to be as big as possible. Note, that lahub and lahubina can perform workouts with different speed, so the number of cells that they use to reach meet cell may differs.

#### Input

The first line of the input contains two integers n and m ( $3 \le n, m \le 1000$ ). Each of the next n lines contains m integers: j-th number from i-th line denotes element a[i][j] ( $0 \le a[i][j] \le 10^5$ ).

#### **Output**

The output contains a single number — the maximum total gain possible.

#### **Examples**

input		
3 3 100 100 100 100 1 100 100 100 100		
output		
800		

#### **Note**

lahub will choose exercises  $a[1][1] \rightarrow a[1][2] \rightarrow a[2][2] \rightarrow a[3][2] \rightarrow a[3][3]$ . lahubina will choose exercises  $a[3][1] \rightarrow a[2][1] \rightarrow a[2][2] \rightarrow a[2][3] \rightarrow a[1][3]$ .

# C. Guess the Tree

time limit per test: 1 second memory limit per test: 256 megabytes

input: standard input output: standard output

lahub and lahubina went to a picnic in a forest full of trees. Less than 5 minutes passed before lahub remembered of trees from programming. Moreover, he invented a new problem and lahubina has to solve it, otherwise lahub won't give her the food.

lahub asks lahubina: can you build a rooted tree, such that

- each internal node (a node with at least one son) has at least two sons;
- node *i* has *C<sub>i</sub>* nodes in its subtree?

lahubina has to guess the tree. Being a smart girl, she realized that it's possible no tree can follow lahub's restrictions. In this way, lahub will eat all the food. You need to help lahubina: determine if there's at least one tree following lahub's restrictions. **The required tree must contain** *n* **nodes**.

## Input

The first line of the input contains integer n ( $1 \le n \le 24$ ). Next line contains n positive integers: the i-th number represents  $C_i$  ( $1 \le C_i \le n$ ).

## **Output**

Output on the first line "YES" (without quotes) if there exist at least one tree following lahub's restrictions, otherwise output "NO" (without quotes).

## **Examples**

NO

input			
4 1 1 1 4			
output			
YES			
input			
5 1 1 5 2 1			
output			

# D. Tricky Function

time limit per test: 2 seconds memory limit per test: 256 megabytes

input: standard input output: standard output

lahub and Sorin are the best competitive programmers in their town. However, they can't both qualify to an important contest. The selection will be made with the help of a single problem. Blatnatalag, a friend of lahub, managed to get hold of the problem before the contest. Because he wants to make sure lahub will be the one qualified, he tells lahub the following task.

You're given an (1-based) array a with n elements. Let's define function f(i,j)  $(1 \le i,j \le n)$  as  $(i-j)^2 + g(i,j)^2$ . Function g is calculated by the following pseudo-code:

```
int g(int i, int j) { 
 int sum = 0; 
 for (int k = min(i, j) + 1; k <= max(i, j); k = k + 1) 
 sum = sum + a[k]; 
 return sum; 
} 
Find a value min_{i \neq j} f(i, j).
```

Probably by now lahub already figured out the solution to this problem. Can you?

#### Input

The first line of input contains a single integer n ( $2 \le n \le 100000$ ). Next line contains n integers a[1], a[2], ..., a[n] ( $-10^4 \le a[i] \le 10^4$ ).

## **Output**

Output a single integer — the value of  $min_{i \neq j}$  f(i, j).

## **Examples**

```
input
4
1 0 0 -1
output
1
```

```
input
2
1 -1

output
2
```

# E. Points and Segments

time limit per test: 1 second memory limit per test: 256 megabytes input: standard input

output: standard output

lahub isn't well prepared on geometry problems, but he heard that this year there will be a lot of geometry problems on the IOI selection camp. Scared, lahub locked himself in the basement and started thinking of new problems of this kind. One of them is the following.

lahub wants to draw n distinct segments  $[I_i, r_i]$  on the OX axis. He can draw each segment with either red or blue. The drawing is good if and only if the following requirement is met: for each point X of the OX axis consider all the segments that contains point X; suppose, that  $r_X$  red segments and  $b_X$  blue segments contain point X; for each point X inequality  $|r_X - b_X| \le 1$  must be satisfied.

A segment [I, r] contains a point X if and only if  $I \le X \le r$ .

lahub gives you the starting and ending points of all the segments. You have to find any good drawing for him.

## Input

The first line of input contains integer n ( $1 \le n \le 10^5$ ) — the number of segments. The i-th of the next n lines contains two integers  $l_i$  and  $r_i$  ( $0 \le l_i \le r_i \le 10^9$ ) — the borders of the i-th segment.

It's guaranteed that all the segments are distinct.

## **Output**

If there is no good drawing for a given test, output a single integer -1. Otherwise output n integers; each integer must be 0 or 1. The i-th number denotes the color of the i-th segment (0 is red and 1 is blue).

If there are multiple good drawings you can output any of them.

## **Examples**
